| A | 0 | 7 |
| B | 4 | 4 |
| C | 5 | 1 |
| D | 9 | 1 |
| E | 12 | 3 |

Preemptive, based on time left in burst.
Easy if you know burst length. In practice, you must estimate.

A form of priority algorithm, where priority is determined by (estimated) remaining burst length.

## 

 Problem DataUse burst time to automatically determine priority. The longer the burst, the lower

| Process | Start | Burst Time t |
| :---: | :---: | :---: |
| A | 0 | 7 |
| B | 4 | 4 |
| C | 5 | 1 |
| D | 9 | 1 |
| E | 12 | 3 | the priority.

Use multiple queues, each sorted by arrival order. Choose first process from highest level queue. Number of queues, $Q=3$.

Always preemptive. Here, quantum $\mathrm{q}=2$.
